# Announcements

- HW 01 due TODAY at 11:59p
- Reading 03 for Monday
- HW 02 due Wednesday, 9/25 at 11:59p

# Today's Agenda

- Introducing multiple linear regression

# R Packages used in the notes

```
library(tidyverse)
library(knitr)
library(broom)
library(Sleuth3) # case 1202 dataset
library(cowplot) # use plot_grid function
```

# Multiple Linear Regression

# Example: Starting Wages

- In the 1970s Harris Trust and Savings Bank was sued for discrimination on the basis of gender.
- The defense presented an analysis of the salaries for skilled, entry-level clerical employees as evidence.
- **Question:** Did female employees receive lower starting salaries on average than male employees with similar experience and qualifications?

# Data

```
glimpse(wages)
```

```
## Observations: 93
```

```
## Variables: 6
```

```
## $ Bsal    <int> 5040, 6300, 6000, 6000, 6000, 6840, 8100, 6000, 6000, 6900,
```

```
## $ Senior  <int> 96, 82, 67, 97, 66, 92, 66, 82, 88, 75, 89, 91, 66, 86, 90,
```

```
## $ Age      <int> 329, 357, 315, 354, 351, 374, 369, 363, 555, 416, 481, 330,
```

```
## $ Educ     <int> 15, 15, 15, 12, 12, 15, 16, 12, 12, 15, 12, 15, 15, 15, 15,
```

```
## $ Exper   <dbl> 14.0, 72.0, 35.5, 24.0, 56.0, 41.5, 54.5, 32.0, 252.0, 13.0,
```

```
## $ Female  <fct> 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 1, 1, 1, 1, 1,
```

# Variables

## Explanatory

- **Educ:** years of education
- **Exper:** months of previous work experience (before hire at bank)
- **Female:** 1 if female, 0 if male
- **Senior:** months worked at bank since hire
- **Age:** age in months

## Response

- **Bsal:** annual salary at time of hire

# Salary comparison

- **Question:** Did female employees receive lower starting salaries on average than male employees with similar experience and qualifications?

# Using ANOVA

$$H_0 : \mu_F = \mu_M$$

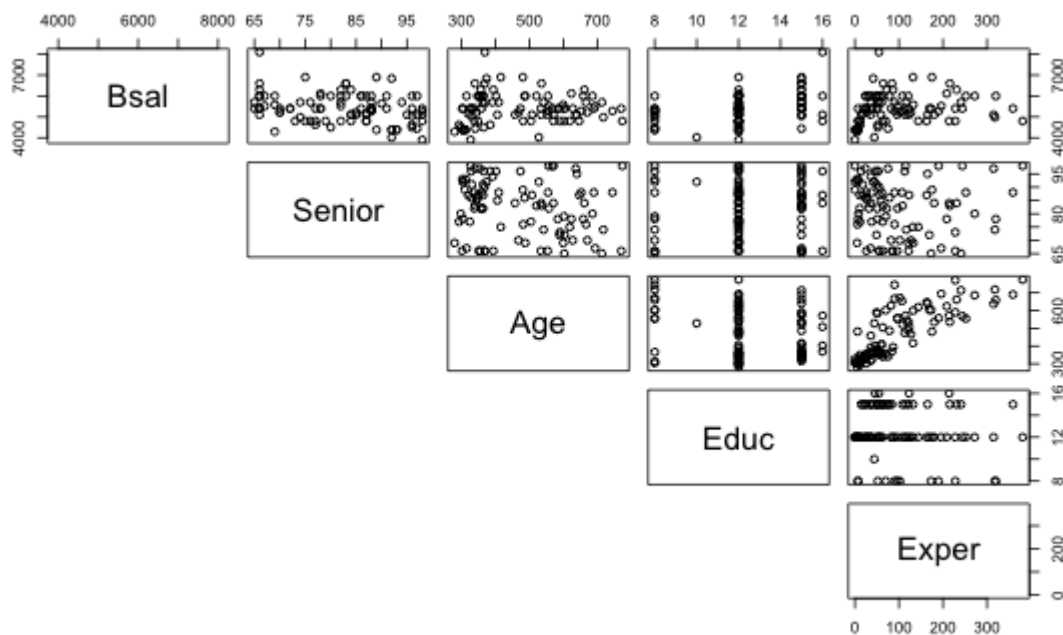

$$H_a : \mu_F \neq \mu_M$$

term	df	sumsq	meansq	statistic	p.value
Female	1	14045183	14045183.2	39.597	0
Residuals	91	32278107	354704.5	NA	NA

- What's your conclusion?
- What is a disadvantage to using this method to answer the question?

# Salary vs. Other Variables

```
pairs(Bsal ~ Senior + Age + Educ + Exper, data=wages,  
      lower.panel = NULL)
```

# Multiple Regression Model

- We will calculate a multiple linear regression model with the following form:

$$Bsal = \beta_0 + \beta_1 \text{Senior} + \beta_2 \text{Age} + \beta_3 \text{Educ} + \beta_4 \text{Exper} + \beta_5 \text{Female}$$

- Similar to simple linear regression, this model assumes that at each combination of the predictor variables, the values *Bsal* follow a Normal distribution

# Regression Model

- Recall: The simple linear regression model assumes

$$y|x \sim N(\beta_0 + \beta_1 x, \sigma^2)$$

- Similarly: The multiple linear regression model assumes

$$y|x_1, x_2, \dots, x_p \sim N(\beta_0 + \beta_1 x_1 + \beta_2 x_2 + \dots + \beta_p x_p, \sigma^2)$$

- For a given observation  $(x_{i1}, x_{i2}, \dots, x_{ip}, y_i)$

$$y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \dots + \beta_p x_{ip} + \epsilon_i \quad \epsilon_i \sim N(0, \sigma^2)$$

# Regression Model

- At any combination of  $x'$ s, the true mean value of  $y$  is

$$\mu_y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_p x_p$$

- We will use multiple linear regression to estimate the mean  $y$  for any combination of  $x'$ s

$$\hat{y} = \hat{\beta}_0 + \hat{\beta}_1 x_1 + \hat{\beta}_2 x_2 + \cdots + \hat{\beta}_p x_p$$

# Regression Output

```
bsal_model <- lm(Bsal ~ Senior + Age + Educ + Exper + Female,  
  data=wages)  
kable(tidy(bsal_model),format="html",digits=3)
```

term	estimate	std.error	statistic	p.value
(Intercept)	6277.893	652.271	9.625	0.000
Senior	-22.582	5.296	-4.264	0.000
Age	0.631	0.721	0.876	0.384
Educ	92.306	24.864	3.713	0.000
Exper	0.501	1.055	0.474	0.636
Female1	-767.913	128.970	-5.954	0.000

# Interpreting $\hat{\beta}_j$

- An estimated coefficient  $\hat{\beta}_j$  is the amount  $y$  is expected to change when  $x_j$  increases by one unit **holding the values all other predictor variables constant**
- *Example:* The estimated coefficient for Educ is 92.31. This means for each additional year of education an employee has, we expect starting salary to increase by about \$92.31, holding all other predictor variables constant.

# Hypothesis Tests for $\hat{\beta}_j$

- We want to test whether a particular coefficient has a value of 0 in the population, given all other variables in the model:

$$H_0 : \beta_j = 0$$

$$H_a : \beta_j \neq 0$$

- The test statistic reported in R is the following:

$$\text{test statistic} = t = \frac{\hat{\beta}_j - 0}{SE(\hat{\beta}_j)}$$

# Salary

term	estimate	std.error	statistic	p.value
(Intercept)	6277.893	652.271	9.625	0.000
Senior	-22.582	5.296	-4.264	0.000
Age	0.631	0.721	0.876	0.384
Educ	92.306	24.864	3.713	0.000
Exper	0.501	1.055	0.474	0.636
Female1	-767.913	128.970	-5.954	0.000

Given the other variables in the model, are the following significant predictors of salary at time of hire (Bsal)?

- Education (Educ)
- Experience (Exper)

# Confidence Interval for $\beta_j$

The  $C$  confidence interval for  $\beta_j$

$$\hat{\beta}_j \pm t^* SE(\hat{\beta}_j)$$

where  $t^*$  follows a  $t$  distribution with  $(n - p - 1)$  degrees of freedom

- **General Interpretation:** We are  $C$  confident that the interval LB to UB contains the population coefficient of  $x_j$ . Therefore, for every one unit increase in  $x_j$ , we expect  $y$  to change LB to UB units, holding all else constant.

## CI for Educ

term	estimate	std.error	statistic	p.value	conf.low	conf.high
(Intercept)	6277.893	652.271	9.625	0.000	4981.434	7574.353
Senior	-22.582	5.296	-4.264	0.000	-33.108	-12.056
Age	0.631	0.721	0.876	0.384	-0.801	2.063
Educ	92.306	24.864	3.713	0.000	42.887	141.725
Exper	0.501	1.055	0.474	0.636	-1.597	2.598
Female1	-767.913	128.970	-5.954	0.000	-1024.255	-511.571

Interpret the 95% confidence interval for the coefficient of Educ.

# Notes about CI and Hypothesis Tests

- If the sample size is large enough, the test will likely result in rejecting  $H_0 : \beta_j = 0$  even  $x_j$  has a very small effect on  $y$ 
  - Consider the **practical significance** of the result not just the statistical significance
  - Use the confidence interval to draw conclusions instead of p-values
- If the sample size is small, there may not be enough evidence to reject  $H_0 : \beta_j = 0$ 
  - When you fail to reject the null hypothesis, **DON'T** immediately conclude that the variable has no association with the response.
  - There may be a linear association that is just not strong enough to detect given your data, or there may be a non-linear association.

# Prediction

- We calculate predictions the same as with simple linear regression
- **Example:** Suppose we want to predict the starting wages for a female who is 28 years old with 12 years of education, 11 months seniority and 2 years of prior experience.

$$\hat{bsal} = 6277.893 - 22.582 \times \text{Senior} + 0.631 \times \text{Age} \\ + 92.306 \times \text{Educ} + 0.501 \times \text{Exper} - 767.913 \times \text{Female}$$

```
6277.893 - 22.582 * 11 + 0.631 * 28 + 92.306 * 12 + 0.501 * 24 - 7
```

```
## [1] 6398.942
```

# Prediction

- Just like with simple linear regression, we can use the `predict.lm()` function in R to calculate the appropriate intervals for our predicted values
- Suppose we want to predict the starting wages for a female who is 28 years old with 12 years of education, 11 months seniority and 2 years of prior experience.

```
x0 <- data.frame(Senior= 11, Age = 28, Educ = 12, Exper = 24, Female = 1)  
predict.lm(bsal_model, x0, interval = "prediction")
```

```
##           fit          lwr          upr  
## 1 6398.93 4967.054 7830.805
```

# Prediction

Suppose we want to predict the mean age for the subset of all females who are 28 years old with 12 years of education, 11 months of seniority and 2 years of prior experience.

- How will the predicted value change?
- How will the interval change?

```
x0 <- data.frame(Senior= 11, Age = 28, Educ = 12, Exper = 24, Female = 1)
predict.lm(bsal_model, x0, interval = "confidence")
```

```
##           fit          lwr          upr
## 1 6398.93 5383.844 7414.016
```

# Cautions

- **Do not extrapolate!** Because there are multiple explanatory variables, you can extrapolation in many ways
- The multiple regression model only shows **association, not causality**
  - To prove causality, you must have a carefully designed experiment or carefully account for confounding variables in an observational study

# Assumptions

# Assumptions

The confidence intervals and hypothesis tests are reliable only when the regression assumptions are reasonably satisfied

1. **Linearity:** Response variable has a linear relationship with the explanatory variables in the model
2. **Constant Variance:** The regression variance is the same for all set of predictor variables  $(x_1, \dots, x_p)$
3. **Normality:** For a given  $(x_1, \dots, x_p)$ , the distribution of  $y$  around its mean is Normal
4. **Independence:** All observations are independent

# Scatterplots

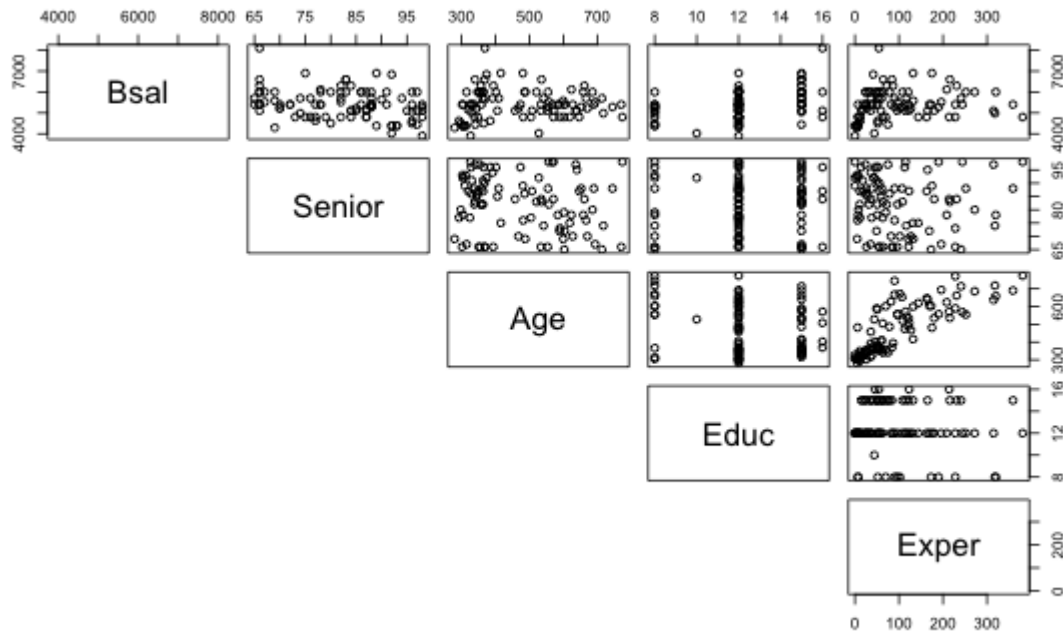

- Look at a scatterplot of the response variable vs. each of the predictor variables in the exploratory data analysis before calculating the regression model
- This is a good way to check for obvious departures from linearity
  - Could be an indication that a higher order term or transformation is needed (will discuss this next class)

# Residual Plots

- Plot the residuals vs. the predicted values
  - Can expose issues such as outliers or nonconstant variance
- Plot the residuals vs. each of the predictors
  - Can expose issues between the response and a predictor variable that didn't show in the exploratory data analysis
  - Use box plots to plot residuals versus categorical predictor variables
- Residual plots should show no systematic pattern
- Plot a histogram and QQ-plot of the residuals to check Normality

# Scatterplots

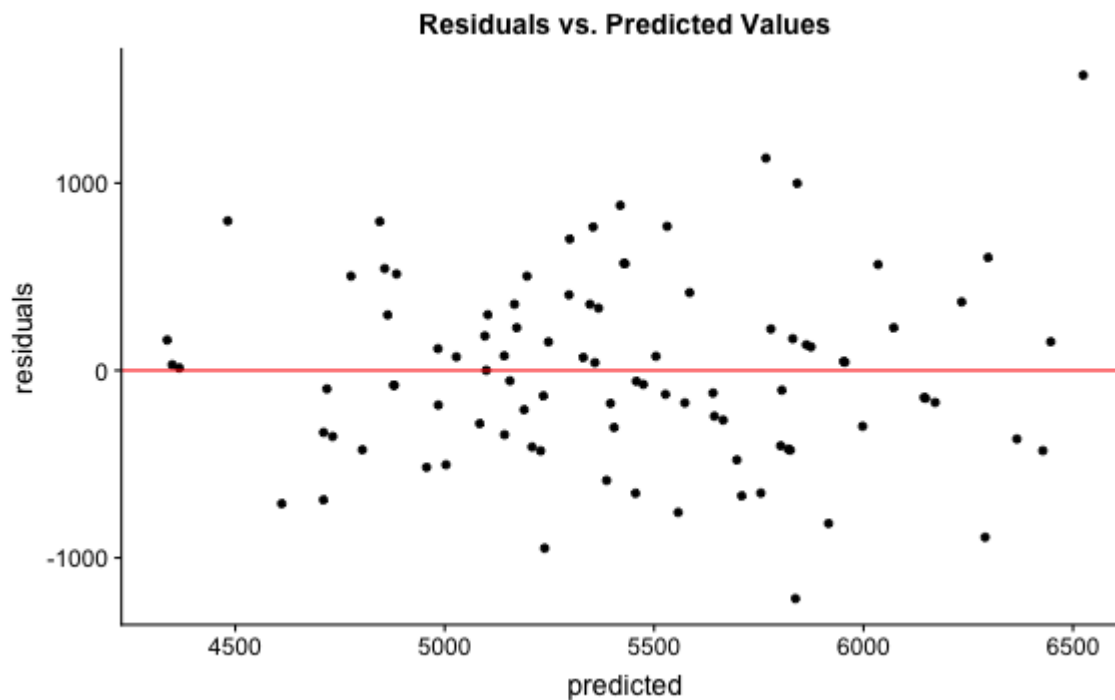

```
pairs(Bsal ~ Senior + Age + Educ + Exper, data = wages,
      lower.panel = NULL)
```

- Only include a few variables in a single pairs plot; otherwise, the scatterplots are too small to be readable.

# Residuals vs. Predicted Values

```
wages <- wages %>%  
  mutate(predicted = predict.lm(bsal_model), residuals = resid(bsal_model))  
ggplot(data=wages, aes(x=predicted, y=residuals)) +  
  geom_point() +  
  geom_hline(yintercept=0, color="red") +  
  labs(title="Residuals vs. Predicted Values")
```

# Residuals vs. Predictors

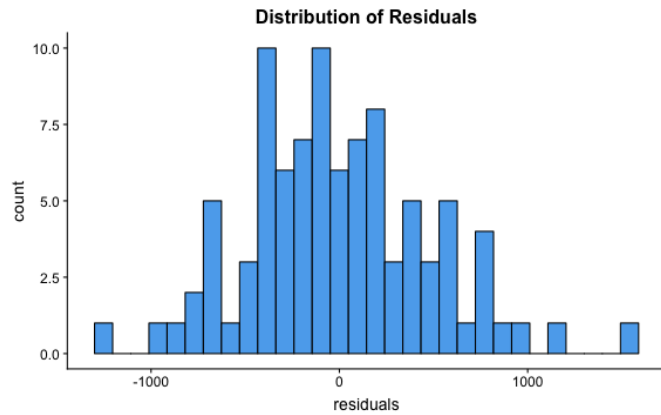

# Residuals vs. Predictors

```
ggplot(data=wages,aes(x=Female,y=residuals)) +  
  geom_boxplot() +  
  geom_hline(yintercept=0,color="red") +  
  labs(x = "Female",  
       y="Residuals")
```

# Normality of Residuals

# Math Foundation

# Regression Model

- The multiple linear regression model assumes

$$y|x_1, \dots, x_p \sim N(\beta_0 + \beta_1 x_1 + \dots + \beta_p x_p, \sigma^2)$$

- For a given observation  $(x_{i1}, \dots, x_{ip}, y_i)$ , we can rewrite the previous statement as

$$y_i = \beta_0 + \beta_1 x_{i1} + \dots + \beta_p x_{ip} + \epsilon_i \quad \epsilon_i \sim N(0, \sigma^2)$$

# Estimating $\sigma^2$

- For a given observation  $(x_{i1}, \dots, x_{ip}, y_i)$  the residual is

$$e_i = y_i - (\hat{\beta}_0 + \hat{\beta}_1 x_{i1} + \dots + \hat{\beta}_p x_{ip})$$

- The **estimated regression variance** is

.alert[

$$\hat{\sigma}^2 = \frac{RSS}{n - p - 1} = \frac{\sum_{i=1}^n [y_i - (\hat{\beta}_0 + \hat{\beta}_1 x_{i1} + \dots + \hat{\beta}_p x_{ip})]^2}{n - p - 1}$$

# Calculating $\hat{\sigma}^2$

Salary: Estimating  $\hat{\sigma}^2$

```
(glance(bsal_model)$sigma)^2
```

```
## [1] 258156
